#### Abstract

In this paper, we formulate a method using Chebyshev polynomials for solving both linear and non-linear multi-point boundary value problems. Quasi linearization technique is used to transform a non-linear boundary value problem into a sequence of linear boundary value problems with a quadratic polynomial which satisfies the boundary conditions chosen as the initial approximation. Four numerical examples are given to demonstrate the efficiency of the present method and the results obtained are compared with other methods in the literatures.

Keywords- Linear and non-linear problems; Multi-point boundary value problem; Chebyshev polynomials; Quasi linearization technique

## 1. INTRODUCTION

In recent years, multi-point boundary value problems have received a considerable growing research interest. Multi-point boundary value problems appear in various areas of sciences and engineering. Modelling and analysing problems arising from electric power networks, railway systems, telecommunication lines, construction of large bridges with many supports and analysing kinetic reaction problems are some examples of physical phenomena that lead to multi-point boundary value problems[8,21]. Many problems in theory of elastic stability can be set up as multi-point boundary value problems [9]. Several numerical methods have been developed for solving multi-point boundary value problems. Some of these are Reproducing kernel method [1,2,5,6,10,11,13], Adomain decomposition method[12], The shooting method [14,15], Weighted residual method[22], Padé approximations[18] and Homotopy perturbation method[23].

Researchers have proposed several methods for handling third-order boundary value problems. For instance, see $[4,12,16,17,18]$ and references therein. However in this paper, we present an approximate method based on Chebyshev polynomials approach for the solution of third-order multi-point boundary value problems of the form

$$
\begin{equation*}
a_{0}(x) y^{\prime \prime \prime}(x)+a_{1}(x) y^{\prime \prime}(x)+a_{2}(x) y^{\prime}(x)+a_{3}(x) y(x)=f(x) \tag{1.1}
\end{equation*}
$$

subject to the boundary conditions

$$
\begin{align*}
& y(0)=\alpha_{1}  \tag{1.2}\\
& y^{\prime}(0)=\alpha_{2}  \tag{1.3}\\
& y^{\prime}(1)=\alpha y^{\prime}(\eta)+\lambda \tag{1.4}
\end{align*}
$$

where $a_{0}(x), a_{1}(x), a_{2}(x), a_{3}(x)$ and $f(x)$ are continuous functions and $\alpha_{1}, \alpha_{2}, \alpha, \lambda$ are constants and $\eta \in(0,1)$.

This paper is organised as follows: In the next section, we define Chebyshev and shifted Chebyshev polynomials of the first and second kinds, establish some relationship between the polynomials of the first and second kinds, describe the derivatives of the shifted Chebyshev polynomials and some of its properties. Section 3 summarizes the application of the proposed method to the solution of problem (1.1) - (1.4). Four numerical examples are given in section 4 to demonstrate the applicability and validity of the method. Finally, the concluding remarks are given in section 5 .

## 2. FORMULATION OF THE METHOD

### 2.1. Definitions of Chebyshev Polynomials

Definition 2.1: The Chebyshev polynomial $T_{n}(x)$ of the first kind is a polynomial of degree $n$ in $x$ defined by

$$
\begin{equation*}
T_{n}(x)=\cos n \theta, \text { where } x=\cos \theta, x \in[-1,1] \tag{2.1}
\end{equation*}
$$

which satisfies the recurrence relation

$$
\begin{equation*}
T_{n}(x)=2 x T_{n-1}(x)-T_{n-2}(x), n \geq 2 \tag{2.2}
\end{equation*}
$$

with the initial conditions

$$
\begin{equation*}
T_{0}(x)=1, \quad T_{1}(x)=x \tag{2.3}
\end{equation*}
$$

Definition 2.2: The shifted Chebyshev polynomial $T_{n}^{*}(x)$ of the first kind on $[0,1]$ is a polynomial of degree $n$ in $x$ defined by

$$
\begin{equation*}
T_{n}^{*}(x)=T_{n}(2 x-1) \tag{2.4}
\end{equation*}
$$

Similarly, $T_{n}^{*}(x)$ satisfies the recurrence relation

$$
\begin{equation*}
T_{n}^{*}(x)=2(2 x-1) T_{n-1}^{*}(x)-T_{n-2}^{*}(x), n \geq 2 \tag{2.5}
\end{equation*}
$$

with the initial conditions

$$
\begin{equation*}
T_{0}^{*}(x)=1, \quad T_{1}^{*}(x)=2 x-1 \tag{2.6}
\end{equation*}
$$

Definition 2.3: The Chebyshev polynomial $U_{n}(x)$ of the second kind is a polynomial of degree $n$ in $x$ defined by

$$
\begin{equation*}
U_{n}(x)=\frac{\sin (n+1) \theta}{\sin \theta}, \text { where } x=\cos \theta, x \in[-1,1] \tag{2.7}
\end{equation*}
$$

The Chebyshev polynomials of the second kind are defined by the recurrence relation

$$
\begin{equation*}
U_{n}(x)=2 x U_{n-1}(x)-U_{n-2}(x), n \geq 2 \tag{2.8}
\end{equation*}
$$

with the initial conditions

$$
\begin{equation*}
U_{0}(x)=1, \quad U_{1}(x)=2 x \tag{2.9}
\end{equation*}
$$

Definition 2.4: The shifted Chebyshev polynomial $U_{n}^{*}(x)$ of the second kind on [0,1] is a polynomial of degree $n$ in $x$ defined by

$$
\begin{equation*}
U_{n}^{*}(x)=U_{n}(2 x-1) \tag{2.10}
\end{equation*}
$$

The shifted Chebyshev polynomials of the second kind are defined by recursively by

$$
\begin{equation*}
U_{n}^{*}(x)=2(2 x-1) U_{n-1}^{*}(x)-U_{n-2}^{*}(x), n \geq 2 \tag{2.11}
\end{equation*}
$$

with the initial conditions

$$
\begin{equation*}
U_{0}^{*}(x)=1, \quad U_{1}^{*}(x)=2(2 x-1) \tag{2.12}
\end{equation*}
$$

### 2.2 Relation between Chebyshev polynomials of the first and second kinds

The following theorems show relationships between the shifted Chebyshev polynomial of the first and second kinds.

## Theorem 2.1

Let $T_{n}^{*}(x)$ and $U_{n}^{*}(x)$ denote the shifted Chebyshev polynomials of degree $n$ in $x$ on $[0,1]$ of the first and second kinds respectively. Then for $n \geq 1, \int 2 U_{n-1}^{*}(x) d x=\frac{1}{n} T_{\mathrm{n}}^{*}(x)+c$, where c is an arbitrary constant.

## Proof

The Chebyshev polynomial of the second kind of degree $n-1$ is defined by

$$
\begin{equation*}
U_{n-1}(x)=\frac{\sin n \theta}{\sin \theta} \text {, where } x=\cos \theta, x \in[-1,1] \tag{2.13}
\end{equation*}
$$

## RECENT

SCIENCE

Integrating both sides of (2.13), we obtain

$$
\int U_{n-1}(x) d x=\frac{\cos n \theta}{n}+c
$$

Thus,

$$
\begin{equation*}
\int U_{n-1}(x) d x=\frac{1}{n} T_{n}(x)+c \tag{2.14}
\end{equation*}
$$

We now use the transformation $x=2 t-1$ to map $x \in[-1,1]$ to $t \in[0,1]$, then (2.14) becomes

$$
\int 2 U_{n-1}(2 t-1) d t=\frac{1}{n} T_{n}(2 t-1)+c
$$

And since $t$ is a dummy variable, we obtain

$$
\begin{equation*}
\int 2 U_{n-1}^{*}(x) d x=\frac{1}{n} T_{n}^{*}(x)+c \tag{2.15}
\end{equation*}
$$

## Theorem 2.2

Let $T_{n}^{*}(x)$ and $U_{n}^{*}(x)$ denote the shifted Chebyshev polynomials of degree $n$ in $x$ on $[0,1]$ of the first and second kinds respectively. Then $U_{n-1}^{*}(x)=2 T_{n-1}^{*}(x)+U_{n-3}^{*}(x), n \geq 3$,

## Proof

From the trigonometry identity

$$
\sin (n+1) \theta-\sin (n-1) \theta=2 \cos n \theta \sin n \theta
$$

Dividing both sides by $\sin \theta$, we obtain

$$
U_{n}(x)=2 T_{n}(x)+U_{n-2}(x)
$$

Replacing $n$ with $n-1$, we have

$$
\begin{equation*}
U_{n-1}(x)=2 T_{n-1}(x)+U_{n-3}(x), n \geq 3 \tag{2.16}
\end{equation*}
$$

Now for $x \in[0,1],(2.16)$ becomes

$$
U_{n-1}(2 x-1)=2 T_{n-1}(2 x-1)+U_{n-3}(2 x-1), n \geq 3
$$

Hence,

$$
\begin{equation*}
U_{n-1}^{*}(x)=2 T_{n-1}^{*}(x)+U_{n-3}^{*}(x), n \geq 3 \tag{2.17}
\end{equation*}
$$

## Theorem 2.3

For $n \geq 1, U_{n-1}^{*}(x)=2 \sum_{\substack{r=0 \\(n-r) \text { odd }}}^{n-1} T_{r}^{*}(x)$,
where $T_{r}^{*}(x)$ and $U_{n}^{*}(x)$ denote the shifted Chebyshev polynomials of degrees $r$ and $n$ in $x$ on $[0,1]$ of the first and second kinds respectively.

## Proof

It follows from (2.17) that

$$
\left.\begin{array}{c}
U_{n-3}^{*}(x)=2 T_{n-3}^{*}(x)+U_{n-5}^{*}(x) \\
U_{n-5}^{*}(x)=2 T_{n-5}^{*}(x)+U_{n-7}^{*}(x) \\
\vdots  \tag{2.18}\\
U_{3}^{*}(x)=2 T_{3}^{*}(x)+2 T_{1}^{*}(x) \text { for } n=4 \\
\text { or } \\
U_{2}^{*}(x)=2 T_{2}^{*}(x)+T_{0}^{*}(x) \text { for } n=3
\end{array}\right\}
$$

Suppose $n$ is odd in (2.17), substituting (2.18) appropriately into (2.17) gives

$$
\begin{equation*}
U_{n-1}^{*}(x)=2\left(T_{n-1}^{*}(x)+T_{n-3}^{*}(x)+T_{n-5}^{*}(x)+\cdots T_{2}^{*}(x)+1 / 2 T_{0}^{*}(x)\right) \tag{2.19}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
U_{n-1}^{*}(x)=2 \sum_{r=0}^{n-1} T_{r}^{*}(x), \tag{2.20}
\end{equation*}
$$

where $r$ is even and a summation symbol with prime denotes a sum with first term halved.
Similarly suppose $n$ is even, we obtain

$$
\begin{equation*}
U_{n-1}^{*}(x)=2 \sum_{r=1}^{n-1} T_{r}^{*}(x) \tag{2.21}
\end{equation*}
$$

where $r$ is odd.
Now equations (2.20) and (2.21) can be written as a single equation as

$$
\begin{equation*}
U_{n-1}^{*}(x)=2 \sum_{\substack{r=0 \\(n-r) \text { odd }}}^{n-1} T_{r}^{*}(x) \tag{2.22}
\end{equation*}
$$

### 2.4 Derivatives of Chebyshev Polynomials

Derivatives of the shifted Chebyshev polynomials $T_{n}^{*}(x)$ of the first kind in the range $[0,1]$ are obtained as follows: Differentiating both sides of (2.15) with respect to $x$, we get

$$
\begin{equation*}
\frac{d}{d x} T_{n}^{*}(x)=2 n U_{n-1}^{*}(x) \tag{2.23}
\end{equation*}
$$

Substituting equations (2.22) into (2.23), we get

$$
\begin{equation*}
\frac{d}{d x} T_{n}^{*}(x)=4 n \sum_{\substack{r=0 \\(n-r) \text { odd }}}^{n-1} T_{r}^{*}(x) \tag{2.24}
\end{equation*}
$$

Differentiating both sides of (2.24) with respect to $x$, we obtain after some algebraic manipulations,

$$
\begin{equation*}
\frac{d^{2}}{d x^{2}} T_{n}^{*}(x)=4 \sum_{\substack{r=0 \\(n-r) \text { even }}}^{n-2} n\left(n^{2}-r^{2}\right) T_{r}^{*}(x) \tag{2.25}
\end{equation*}
$$

Likewise for the third derivative, we have

$$
\begin{equation*}
\frac{d^{3}}{d x^{3}} T_{n}^{*}(x)=16 \sum_{l=0}^{n-3}, \sum_{\substack{r=l+1 \\(n-r) \text { even }}}^{n-2} n r\left(n^{2}-r^{2}\right) T_{l}^{*}(x) \tag{2.26}
\end{equation*}
$$

### 2.3 Some Properties of Chebyshev Polynomials

## Theorem 2.4

$T_{n}^{*}(x) \quad$ of $\quad$ degree $\quad n \geq 1$ assumes its $n+1$ extrema in $\quad[0,1] \quad$ at $\quad x_{j}=\frac{1}{2}\left(1+\cos \left(\frac{j \pi}{n}\right)\right)$ with $T_{n}\left(x_{j}\right)=(-1)^{j}$, for each $j=0,1, \ldots ., n$.

## Proof

We use a property of $\cos (x)$ to determine the extrema of the shifted Chebyshev polynomial. Recall that the extrema occur when $\cos (\theta)= \pm 1$ which is a multiple of $\pi$. If we then set $n \cos ^{-1}\left(2 x_{j}-1\right)=j \pi$. This implies that

$$
\begin{equation*}
x_{j}=\frac{1}{2}\left(1+\cos \left(\frac{j \pi}{n}\right)\right), j=0,1, \ldots ., n \tag{2.27}
\end{equation*}
$$

Also,

$$
\cos \left(n \cos ^{-1}\left(2 x_{j}-1\right)\right)=\cos j \pi=(-1)^{j}
$$

Thus,

$$
\begin{equation*}
T_{n}^{*}\left(x_{j}\right)=(-1)^{j}, j=0,1, \ldots, n \tag{2.28}
\end{equation*}
$$

From (2.28) we obtain for $j=n$ and $j=0$, respectively

$$
\begin{equation*}
T_{n}^{*}(0)=(-1)^{n}, n \geq 1 \tag{2.29}
\end{equation*}
$$

and

$$
\begin{equation*}
T_{n}^{*}(1)=1, n \geq 1 \tag{2.30}
\end{equation*}
$$

Evaluating (2.24) at the two endpoints, we obtain the following important results:

$$
\begin{align*}
& \left.\frac{d}{d x} T_{n}^{*}(x)\right|_{x=0}=(-1)^{n+1} 2 n^{2}, n \geq 0  \tag{2.12}\\
& \left.\frac{d}{d x} T_{n}^{*}(x)\right|_{x=1}=2 n^{2}, n \geq 0 \tag{2.13}
\end{align*}
$$

## 3. IMPLEMENTATION OF THE METHOD

In order to solve equation (1.1) with the boundary conditions (1.2) - (1.4), we approximate $y(x)$ using the finite sum

$$
\begin{equation*}
y_{n}(x)=\sum_{k=0}^{n} c_{k} T_{k}^{*}(x) \tag{3.1}
\end{equation*}
$$

where $c_{k}$ are constants to be determined.
Substituting (3.1) and its derivatives into (1.1), we obtain

$$
\begin{align*}
& 16 a_{0}(x) \sum_{k=3}^{n} \sum_{\substack{l=0 \\
(k-r)}}^{k-3 v e n}, \sum_{\substack{r=1+1}}^{k-2} k r\left(k^{2}-r^{2}\right) c_{k} T_{l}^{*}(x)+4 a_{1}(x) \sum_{k=2}^{n} \sum_{\substack{r=0 \\
(k-r) \text { even }}}^{k-2} k\left(k^{2}-r^{2}\right) c_{k} T_{r}^{*}(x) \\
& \quad+4 a_{2}(x) \sum_{k=1}^{n} \sum_{\substack{r=0 \\
(k-r) \text { odd }}}^{k-1,} k c_{k} T_{r}^{*}(x)+a_{3}(x) \sum_{k=0}^{n} c_{k} T_{r}^{*}(x)=f(x) \tag{3.2}
\end{align*}
$$

We have to select $n-2$ points in the range of integration such that $y_{n}(x)$ satisfies the differential equation (1.1) at these $n-2$ collocation points and the boundary conditions (1.2) - (1.4).

Setting $x=x_{j}$ in (3.2), we obtain

$$
\begin{align*}
& 16 a_{0}\left(x_{j}\right) \sum_{k=3}^{n} \sum_{\substack{l=0 \\
(k-r) \text { even }}}^{k-3} \sum_{\substack{r=1}}^{k-2} k r\left(k^{2}-r^{2}\right) r c_{k} T_{l}^{*}\left(x_{j}\right)+4 a_{1}\left(x_{j}\right) \sum_{k=2}^{n} \sum_{\substack{r=0 \\
(k-r) \text { even }}}^{k-2} k\left(k^{2}-r^{2}\right) c_{k} T_{r}^{*}\left(x_{j}\right) \\
& +4 a_{2}\left(x_{j}\right) \sum_{k=1}^{n} \sum_{\substack{r=0 \\
(k-r) \text { odd }}}^{k-1,} k c_{k} T_{r}^{*}\left(x_{j}\right)+a_{3}\left(x_{j}\right) \sum_{k=0}^{n} c_{k} T_{r}^{*}\left(x_{j}\right)=f\left(x_{j}\right), \tag{3.3}
\end{align*}
$$

where $x_{j}$ are firstly chosen as the evenly spaced points

$$
\begin{equation*}
x_{j}=\frac{j}{n-1}, j=1,2, \ldots, n-2 . \tag{3.4}
\end{equation*}
$$

Secondly, to achieve higher accuracy we use unevenly distributed nodes. In this case, the collocation points are chosen to be the internal extrema

$$
\begin{equation*}
x_{j}=\frac{1}{2}\left(1+\cos \left(\frac{j \pi}{n-1}\right)\right), j=1,2, \ldots, n-2 \tag{3.5}
\end{equation*}
$$

of the $(n-1)$ th order shifted Chebyshev polynomial $T_{n-1}^{*}(x)$.
Now, the boundary conditions (1.2) - (1.4) yield respectively

$$
\begin{align*}
& \sum_{k=0}^{n}(-1)^{k} c_{k}=\alpha_{1}  \tag{3.6}\\
& \sum_{k=0}^{n}(-1)^{k+1} 2 k^{2} c_{k}=\alpha_{2}  \tag{3.7}\\
& \sum_{k=0}^{n} 2 k^{2} c_{k}=4 \alpha \sum_{k=1}^{n} \sum_{\substack{r=0 \\
(k-r) \text { odd }}}^{k-1}, k c_{k} T_{r}^{*}(\eta)+\lambda \tag{3.8}
\end{align*}
$$

Therefore, the $n-2$ equations obtained in (3.3) plus the 3 boundary conditions (3.6) - (3.8) give the system of ( $\mathrm{n}+1$ ) equations which is solved for the unknown coefficients $c_{k}, k=0,1, \ldots, n$ in (3.1).

## 4. NUMERICAL EXAMPLES

In this section, two linear and two non-linear examples are examined to test the efficiency of the proposed method. The results obtained show that the method with nonuniformly- distributed nodes gives a better result. All computations are carried out with matlab 2010a.

## Problem 4.1

Consider the following linear third-order boundary value problem[19, 1, 3, 7]

$$
\begin{equation*}
y^{\prime \prime \prime}-x y=\left(x^{3}-2 x^{2}-5 x-3\right) e^{x} \tag{4.1}
\end{equation*}
$$

Subject to the boundary conditions

$$
\begin{equation*}
y(0)=0, y^{\prime}(0)=1, y^{\prime}(1)=-e \tag{4.2}
\end{equation*}
$$

The exact solution is $y(x)=x(1-x) e^{x}$. We report absolute errors of our method for $n=8$ and $n=10$ with the two sets of grid points together with the results obtained in [1] at some selected points.

## Problem 4.2

Consider the following variable coefficient non-homogeneous linear third-order boundary value problem [1]

$$
\begin{equation*}
y^{\prime \prime \prime}(x)+x y^{\prime \prime}(x)=-6 x^{2}+3 x-6 \quad 0 \leq x \leq 1 \tag{4.3}
\end{equation*}
$$

Subject to the boundary conditions

## RECENT <br> SCIENCE

$$
\begin{equation*}
y(0)=0, y^{\prime}(0)=1, y^{\prime}(1)=y^{\prime}\left(\frac{1}{2}\right)-\frac{3}{4} \tag{4.4}
\end{equation*}
$$

The exact solution is $y(x)=\frac{3}{2} x^{2}-x^{3}$. The numerical results by our method for $n=3$ with either way of choosing the grid points (i.e. equation (3.4) or (3.5)) are presented in Table 2. We compare the absolute errors of the proposed method with the method of Akram et al[1].

## Problem 4.3

Consider the following non-linear third-order boundary value problem [1, 4]

$$
\begin{equation*}
y^{\prime \prime \prime}(x)+2 e^{-3 y}=4(1+x)^{-3} \tag{4.5}
\end{equation*}
$$

Subject to the boundary conditions

$$
\begin{equation*}
y(0)=0, y^{\prime}(0)=1, y^{\prime}(1)=\frac{1}{2} \tag{4.6}
\end{equation*}
$$

The exact solution is $y(x)=\ln (1+x)$. The nonlinear boundary value problem (4.5)-(4.6) is linearized by the quasilinearization technique [20] to obtain

$$
\begin{equation*}
y_{k+1}^{i i i}-6 e^{-3 y_{k}} y_{k+1}=-6 e^{-3 y_{k}} y_{k}-2 e^{-3 y_{k}}+4(1+x)^{-3}, k=0,1, \ldots \tag{4.7}
\end{equation*}
$$

subject to $y_{k+1}(0)=0, y_{k+1}^{i}(0)=1, \quad y_{k+1}^{i}(1)=\frac{1}{2}$
Using the initial approximation $y_{0}(x)=x-\frac{1}{4} x^{2}$, the numerical results for this problem at third iteration (i.e. $k=2$ ) at some selected points are presented in Table 3 for both $n=8$ and $n=10$, and in comparison with the results obtained in Khan and Aziz[4] and Akram et al[1].

## Problem 4.4

Consider the following non-homogenous non-linear third-order boundary value problem

$$
\begin{equation*}
y^{\prime \prime \prime}(x)+\left(y^{\prime \prime}(x)\right)^{2}=\sin ^{2} x-\cos x \quad 0 \leq x \leq 1 \tag{4.9}
\end{equation*}
$$

Subject to the boundary conditions

$$
\begin{equation*}
y(0)=0, y^{\prime}(0)=1, y^{\prime}(1)=y^{\prime}\left(\frac{1}{2}\right)+\cos (1)-\cos \left(\frac{1}{2}\right) \tag{4.10}
\end{equation*}
$$

The exact solution is $y(x)=\sin x$. Linearizing the nonlinear boundary value problem (4.9)-(4.10) by the quasilinearization technique [20], we obtain

$$
\begin{equation*}
y_{k+1}^{i i i}+2 y_{k}^{i i} y_{k+1}^{i i}=\left(y_{k}^{i i}\right)^{2}+\sin ^{2} x-\cos x, k=0,1, \ldots \tag{4.11}
\end{equation*}
$$

subject to $y_{k+1}(0)=0, y_{k+1}^{i}(0)=1, \quad y_{k+1}^{i}(1)=y_{k+1}^{i}(1 / 2)+\cos (1)-\cos (1 / 2)$
With the initial approximation $y_{0}(x)=x+(\cos (1)-\cos (1 / 2)) x^{2}$, the numerical results for this problem at fourth iteration (i.e. $k=3$ ) at some selected points are presented in Table 4 for both $n=8$ and $n=10$.

Table 1: Comparison of Absolute Errors in numerical results for Example 4.1

## 5. CONCLUSION

In this paper, we have studied a method based on Chebyshev polynomials of the first kind for solving both linear and non-linear third-order multi-point boundary value problems. Besides the advantage of high accurate results, the proposed method solves the boundary value problem without converting it to a system of first-order differential equations thereby reducing the computational cost.
