- Alpha glucosidase
- *Tephrosia bracteolata*

**A B S T R A C T**

**Aims:** Plant extracts have long been used for the ethnomedical treatment of diabetes, microbial infections and as a source of antioxidant. This study was aimed at investigating the antidiabetic, antioxidant, and antimicrobial activities of the n-hexane and ethyl acetate extract of *Tephrosia bracteolata* leaves (TBL) as associated with the ethnomedical and ethnomedicinal knowledge of the local people of Nigeria.

**Main methods:** The phytochemical composition of the n-hexane and ethyl acetate extract of the leaves of *T. bracteolata* were determined following standard procedures in literature, and it’s in vitro inhibitory activities against α-glucosidase enzyme. 2,2′-azino-bis (3-ethylbenzothiazoline-6-sulphonic acid) (ABTS•−) and 1,1-diphenyl-2-picrylhydrazyl (DPPH•−) antioxidant activities were also examined. Well diffusion method was employed in evaluating the antimicrobial property of the extracts.

**Key findings:** The ethyl acetate extract of *T. bracteolata* leaves had the greatest inhibitory effect on α-glucosidase, followed by the n-hexane with IC₅₀ 43.95 μg/ml and IC₅₀ 50 μg/ml respectively. The ethyl acetate also exhibited significant DPPH•− and ABTS•− antioxidant activity with IC₅₀ of 24.96 μg/ml and 6.48 μg/ml as compared to Ascorbic acid and Trolox (12.24 μg/ml and 5.91 μg/ml) respectively. The zones of inhibition of the ethyl acetate extract of *T. bracteolata* leaves ranges from 10 – 25 mm at a concentration of 6.25–200 mg/ml, and it showed a greater antibacterial activity than the n-hexane extract, having a zone of inhibition from 10 – 20 mm at concentration of 12.5–200 mg/ml when compared to the standard Gentamycin. Similarly, the ethyl acetate extract of *T. bracteolata* showed a better anti fungi activity at concentration range 12.5–200 mg/ml than the n-hexane extract at concentration range of 25–200 mg/ml with reference to Tioconazole. These results indicated for the first time that the ethyl acetate extract of *T. bracteolata* leaves extracts exerted potent inhibitory effects against α-glucosidase, actively scavenge DPPH•− and ABTS•− free radicals and successfully inhibits the proliferation of Gram positive and Gram negative microorganism.

**Significance:** TBL is an important source of antidiabetic, antimicrobial and antioxidant agent.

1. Introduction

Pathogenic micro-organisms have built great resistance against several synthetic antibiotics; as a result, much attention is being paid to isolate biologically active compounds from plant species used in primitive medicine [1]. Thus, offering a new lead towards drug discovery [2]. Extracts from plants have been used since ancient times for the traditional treatment of diabetes, microbial infections, stress related disorder, sources of antioxidant, etc., and now they are widely accepted as supplementary alternative for orthodox drugs [3]. Plants represents majorly the useful dietary supplements for improving blood glucose control and preventing long-term complications in type 2 diabetes mellitus (T2DM)
Therefore, natural α-glucosidase inhibitors are currently a major research focus. In recent past, in vitro studies have been performed giving rise to potential α-glucosidase inhibitors from various natural food and plant sources [6, 7, 8, 9]. Therefore, natural α-glucosidase inhibitors of plant origin offer an interesting control for postprandial hyperglycemia.

*Tephrosia bracteolata* is a useful Plants of West Tropical Africa [10, 11]. It is an herbaceous annual, or shrubby, erect under bush to 1 m high, or more, of open country throughout the Region from Senegal to Nigeria, and widespread in tropical Africa eastwards to Ethiopia and southwards to Angola [12]. The plant has been used for various purposes in folklore medicine. The root is used as medicine for venereal diseases, e.g. treatment of pregnant women with syphils, the aerial parts has been used for animal grazing [13] and, used in Ivory Coast as fish poison [14]. In the northern part of Nigeria, the leaves and roots are used by hunters and warriors for charms against treatment of injury [10]. This study is aimed at determining the antidiabetic, antioxidant and antimicrobial properties of the leaves of *T. bracteolata* since there is dearth of information on its activity.

1. Materials and methods

2. Reagents

Potassium persulfate, 1,1-diphenyl-2-picrylhydrazyl (DPPH), methanol, glucose, BSA (Bovine serum albumin), sodium phosphate buffer, ascorbic acid, ethanol, Acarbose Ascorbic acid, 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid), para-nitrophenyl-alpha-D-glucopyranoside, etc., were purchased from Sigma-Aldrich chemicals, USA, Merck Limited, India and S.D. Fine Chemicals Limited India.

2. Materials

Gram-negative bacteria: *Salmonella typhii* (UCH 4801), *Escherica coli* (UCH 1102) and *Klebsiellae pneumoniae* (UCH 2894) while *Bacillus subtilis* (UCH 74230) and *Staphylococcus aureus* (UCH 2473) are Gram-positive, clinical strains from the Medical Microbiology unit, University College Hospital, Ibadan, were screened at the Department of Pharmaceutical Microbiology laboratory, University of Ibadan, Ibadan, Nigeria. Solvent of n-hexane and ethyl acetate were used as negative controls in the assays. Antimicrobial agents: Gentamycin (10 μg/ml) and Ticonazole (0.7 μg/ml) were included as standard reference drugs in the study.

2.3. Collection of plant

The plant was collected from Jalala Estate, University of Ilorin, Tanke Oke-Odo, Ilorin, Kwara State, Nigeria. The plant materials were taxonomically identified and verified at the Department of Plant Biology, University of Ilorin, Ilorin, where a voucher specimen (UIH004/1189) was deposited.

2.4. Preparation of plant extracts

Fresh leaves of *T. bracteolata* were harvested, weeded, washed, and air-dried under shade. The air-dried leaves were gradiently extracted in n-hexane and ethyl acetate respectively. The n-hexane and ethyl acetate crude extracts were concentrated and stored at 4 °C.

2.5. Preliminary phytochemical screening of *T. bracteolata* leaves extract

The n-hexane extract (TBHL) and the ethyl acetate extract (TbEAL) of the leaves of *T. bracteolata* were each screened for various bioactive pharmaceutical constituents such as anthraquinones, steroids, cardiac glycosides, tannins, saponins, phlobotannins, terpenoids, flavonoids, and alkaloids using standard methods [14, 15].

2.6. Antidiabetic study

The antidiabetic Studies was carried out using Alpha-Glucosidase Inhibition Assay [16]. Briefly, in a 96-well microplate, 20 μL of each extract was incubated with 50 μL of crude intestinal α-glucosidase for 5 min and 50 μL of substrate (5 mM, p-nitrophenyl-α-glucopyranoside, prepared in 100 mM phosphate buffer, pH 6.8) was added. The pale yellow colour due to the release of p-nitrophenol from α-linkage of glucopyranoside by the action of enzyme α-glucosidase was measured spectrophotometrically at 405 nm (BioTek synergy4, BioTek Instruments Inc, Winooski, VT, USA) after incubation for 10 min. An individual blank for each extract was prepared to counterbalance absorbance due to the colour of samples, where, in lieu of enzyme, 50 μL of normal saline was added. Percentage of enzyme inhibition was obtained applying the following formula:

\[
\% \text{Inhibition} = \frac{\text{Absorbance of control} - \text{Absorbance of extract}}{\text{Absorbance of control}} \times 100
\]

The antidiabetic Studies was carried out using Alpha-Glucosidase Inhibition Assay [16]. Acarbose was used as the reference standard.

2.7. Free radical scavenging assay

2.7.1. DPPH free radical scavenging assay

Decolorisation of DPPH radical was determined by reported standard method [11]. In brief, 25 μL of various dilutions of the extracts (n-hexane and ethyl acetate), 100 μL of Tris HCl buffer (0.1 M, pH 7.4) and 125 μL DPPH solution (0.5 mM in methanol) were added in a 96-well micro plate and incubated in the dark for 15 min. Absorbance was recorded at 517 nm, and the percentage of DPPH scavenging by extracts was calculated applying the following formula:

\[
\% \text{Inhibition} = \frac{\text{Absorbance of control} - \text{Absorbance of extract}}{\text{Absorbance of control}} \times 100
\]

Several serial dilutions of respective extracts were prepared and analysed [17]. Ascorbic acid was used as standard. The percentage of DPPH scavenging was calculated as above. The IC\(_{50}\) of the extracts were calculated applying a suitable regression analysis.

2.7.2. ABTS+ scavenging assay

Scavenging of 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) ABTS\(^+\) cation radical was performed with suitable modifications. Briefly, 100 ml stock solution of ABTS\(^+\) (0.5 mM) was prepared by addition of 1 ml potassium persulfate [6.89 mM in Phosphate-buffered saline (PBS) (pH 8.0)]. Mixture was stored in dark for 16 h. 10 μL of each of the different extracts (5 μg/ml in PBS) were added to 190 μL of ABTS\(^+\) in 96-well microplate. Percentage scavenging of ABTS\(^+\) by test samples were calculated as follows using:

\[
\% \text{Inhibition} = \frac{\text{Absorbance of control} - \text{Absorbance of extract}}{\text{Absorbance of control}} \times 100
\]

Necessary calculations were applied to obtain the IC\(_{50}\) [18].

2.8. Antimicrobial assay

Microorganism’s cultures of six human pathogenic bacteria made up of four Gram negative and two Gram positive were used for the antibacterial assay. The Antifungal assay was tested on four fungi: *Candida albicans; Aspergillus niger; Rhizopus stolon;* and *Penicillium notatum.*

Media: Nutrient agar, Sabouraud dextrose agar, nutrient broth and
tryptone soya agar were used in this study.

2.8.1. Antimicrobial activity determination

Agar diffusion-pour plate method (bacteria) [19, 20]. An overnight culture of each organism was prepared by taking two wire loop of the organism from the stock and inoculated each into the sterile nutrient broth of 5ml, each incubated for 18–24 h at 37 °C. From overnight culture, 0.1 ml of each organism was taken and put into the 9.9 ml of sterile distilled water to obtained 10^{-2} inoculum concentration of the organism. From the diluted organism (10^{-2}), 0.2 ml was taken into the prepared sterile nutrient agar cooled to about 40–45 °C, then poured into sterile Petri dishes and allowed to solidify for about 1 h. Using a sterile cork-borer of 8 mm diameter, the wells were made according to the number of the test tubes for the experiment. For this work 8 wells were made. The graded concentrations of the extracts were put into the wells accordingly including the controls. The studies were done in duplicates to ascertain the results obtained. The plates were left on the bench for about 2 h to allow the extract diffuse properly into the nutrient agar i.e. pre-diffusion. The plates were incubated for 18–24 h at 37 °C.

Agar diffusion-surface plate method (fungi): A sterile sabouraud agar plate was prepared and aseptically poured into the sterile plates in triplicates and solidified properly. 0.2 ml of the 10^{-2} inoculum concentration of the organism was spread on the surface of the agar using a sterile Petri-dish to cover all the surface of the agar. Eight wells were bored using a sterile cork-borer of 8 mm diameter. The graded concentrations of the extracts were put into the wells according to the controls. All the plates were left on the bench for 2 h to allow the extract diffuse properly into the agar i.e. pre-diffusion. The plates were incubated at 25 °C for 72 h [19,20].

2.9. Statistical analysis

Results were presented as mean ± standard error of mean (SEM). Statistical analysis was carried out with Graph Pad Prism 6 software, Incorporated, USA. There were significant differences between the extracts and the positive control, it may be less because it's a crude extract accordingly, and aseptically poured into the sterile plates in triplicates and solidified properly. 0.2 ml of the 10^{-2} inoculum concentration of the microorganism was spread on the surface of the agar using a sterile Petri-dish to cover all the surface of the agar. Eight wells were bored using a sterile cork-borer of 8 mm diameter. The graded concentrations of the extracts were put into the wells according to the controls. All the plates were left on the bench for 2 h to allow the extract diffuse properly into the agar i.e. pre-diffusion. The plates were incubated at 25 °C for 72 h [19,20].

3. Results and discussion

3.1. Phytochemical screening

The results of the phytochemical screening carried out on the TbHL and TbEAL extracts of T. bracteolata leaves is shown in Table 1 below. The result revealed the presence of alkaloids, steroids, tannins, flavonoids and terpenoids. The analysis revealed the presence of constituents which are known to exhibit medicinal activities (Lwande et al., 1985).

3.2. Antidiabetic activity

The results of the in vitro α-glucosidase enzyme inhibition assay (Fig. 1) of the TbHL and TbEAL extracts of T. bracteolata leaves revealed moderate antidiabetic activities. TbHL extract of T. bracteolata showed a lower α-glucosidase enzyme percentage inhibition activity (57%), when compared to the TbEAL (67%) extract and the standard, Acarbose (92.95%). Between these two plant extracts, TbEAL extract of T. bracteolata exhibited IC_{50} 43.95 μg/ml as compared to Acarbose 11.31 μg/ml though not statistically significant (p < 0.05) compared to the standard of (Fig. 2). Rajaram and Suresh [21] reported the ethyl acetate stem extract of Tephrosia tinctoria to have shown significant inhibitory activity (IC_{50} 94.33 ± 3.65 μg/ml) compared to standard (Acarbose - IC_{50} 38.92 ± 3.52 μg/ml). The aqueous seed extract of Tephrosia purpurea was reported to have demonstrated significant in vivo antihyperglycemic activity in streptozotocin induced diabetic rats [22]. Likewise, the ethanol extract of Tephrosia villosa leaves showed reduction in glucose level and pancreatic cell regeneration in alloxan induced diabetes in rats [23]. These results also lend credence to the fact that TbEAL extract of T. bracteolata demonstrates anti diabetic activity.

3.3. In vitro antioxidant activities

The results of the in vitro antioxidant activity of TbHL and TbEAL extracts of T. bracteolata presented in Figs. 3 and 4 showed moderate activity respectively as revealed by the DPPH and ABTS + free radical scavenging activity. The TbHL extract of T. bracteolata showed a lower percentage inhibition of DPPH antioxidant activities of (39.29 ± 0.07) when compared to that of the extract of TbEAL (80.12 ± 1.22). The percentage inhibition of TbEAL extract was not significantly different from that of the standard compound, Ascorbic acid (94.23 ± 0.00). Between these two plant extracts, the TbEAL extract of T. bracteolata demonstrated anti diabetic activity.
exhibited significant inhibition of IC_{50} 24.69 μg/ml as compared to the standard compound, Ascorbic acid 12.24 μg/ml. Similarly, the TbHL extract of _T. bracteolata_ showed a lower percentage inhibition of ABTS + antioxidant activities of (11.14 ± 0.36) as compared to that of the TbEAL extract (96.46 ± 0.00). The percentage inhibition of TbEAL extract was not significantly different from that of the standard compound, Trolox (98.73 ± 0.30). The IC_{50} also of TbEAL extract 6.48 μg/ml was also not statistically different from the standard 5.91 μg/ml. From the results discussion above of the two plant extracts, TbEAL extract of _T. bracteolata_ exhibited significant DPPH and ABTS + antioxidant activity IC_{50} of 24.96 μg/ml and 6.48 μg/ml as compared to Ascorbic acid and Trolox (12.24 μg/ml and 5.91 μg/ml) respectively.

The result of the _in vitro_ antioxidant activity of the ethyl acetate extracts of the leaves of _T. bracteolata_ corroborates the fact that the Ethyl acetate fraction of stem of _Tephrosia tinctoria_ exhibited significant antioxidant activity [21]. Other species of the Genus _Tephrosia_ that have been studied includes: the ethanolic extract of _Tephrosia purpurea_ [24, 25], ethyl acetate extracts of _Tephrosia egregia_ [26], _Tephrosia villosa_ [27], the ethanol ether extract of _Tephrosia vogelii_ seeds [28].

### 3.4. Antimicrobial activities

#### 3.4.1. Antibacterial activities

The result of the antibacterial activities of the n-hexane and ethyl acetate extracts at concentrations between 6.25 and 200 mg/ml is presented in Table 2. The antimicrobial activities of the extract in this study varies with the solvent type used in the extraction and the concentrations of the extract used. TbHL extract showed antibacterial activity on _S. aureus_, _B. subtilis_, and _E. coli_, at concentration range of 12.5–25 mg/ml and significant inhibitory effect on all six investigated bacteria at 50–200 mg/ml when compared to the standard, Gentamycin. Similarly, TbEAL extract inhibited the growth of all six bacteria at 12.5–200 mg/ml, except on _E. coli_, where the inhibition concentration ranges from 25 – 200 mg/ml. Furthermore, TbEAL extract, even at 6.25 mg/ml, inhibited the growth of _S. aureus_ and _B. subtilis_ (Gram positive). The TbEAL extract showed a greater antibacterial activity than the TbHL extract.

Several species from Genus _Tephrosia_ have been studied for their antibacterial activity. Kumar [29] investigated the antimicrobial effects of the roots of _Tephrosia purpurea_ against acne-inducing bacteria _Propionibacterium acnes_ and _Staphylococcus epidermidis_. The results from the disc diffusion method they carried out showed that _T. purpurea_ strongly inhibited the growth of _Propionibacterium acnes_. Ganapathy also reported that Pumilanol, an antiprotozoal isoflavonol from _Tephrosia pumila_ exhibited significant antiprotozoal activity against _T. b. rhodensistene_, _T. cruzi_ and _L. donovani_ with IC_{50} of 3.7, 3.35 and 17.2 mg/ml respectively [30]. Li investigated the bacteriostatic activity of extracts in different solvents from _Tephrosia vogelii_ Hook F. seeds and found out that the extracts successfully inhibited the activity of _E. coli_, _S. aureus_ and _S. paratyphi_ B. hence proved the antibacterial efficacy of the plant to be significant at high doses [28].

#### 3.4.2. Antifungal activities

The antifungal activities of the TbHL extracts and TbEAL extracts of _T. bracteolata_ leaves at concentrations between 6.25 and 200 mg/ml is presented in Table 3. Four clinical strains of fungi were used; _Candida albicans_, _Aspergillus niger_, _Rhizopus stolonifer_, and _Penicillium notatum_. The TbHL extract exhibited low antifungal activity on _C. albicans_ even at.

### Table 2

Antibacterial activities of the n-hexane and ethyl acetate extract of _T. bracteolata_ leaves.

Further studies to investigate the bioactive compounds responsible for these observed biological activities may also be the reason why this plant is used as animal feeds. The zone of inhibition of the test bacteria and fungi on both extracts of T. bracteolata showed more activity, as much as 70% inhibition when compared to the positive control. It is very interesting to note that both the methanolic extract was found to be more active against the aforementioned organisms [30], namely *T. purpurea* which showed significant activity against A. niger and C. albicans [32], *Tephrosia hildebrandtii* was shown to have antifungal activity against *C. cucumerinum*. The activity was found to be related to a chemical compound isolated from its roots [33], namely *T. tinctoria* which also showed activity against A. niger, C. albicans. The methanolic extract was found to be more active against the aforementioned organisms [30]. It is very interesting to note that both the n-hexane and the ethyl acetate extract of *T. bracteolata* successfully inhibited the growth of all four tested organisms with the ethyl acetate extract showing more activity, as much as 70% inhibition when compared to the standard drug, Ticonazole.

Thus, following the trend of the antimicrobial activity of *T. bracteolata*, it shows that the plant is a good source of antimicrobial agent. The zone of inhibition of the test bacteria and fungi on both extracts were concentration dependent, that is, activity was higher as concentrations of the extracts increases.

### 4. Conclusion

The results of the in vitro α-glucosidase enzyme inhibition assay and the DPPH and ABTS\(^+\) antioxidant activity of the extracts of *Tephrosia bracteolata* leaves revealed that the leaves exhibited moderate α-glucosidase enzymatic inhibition activities and an appreciable antioxidant activity respectively. The antimicrobial activity exhibited by the n-hexane (TbHL) and ethyl acetate (TbEAL) supports the use of the leaves of *T. bracteolata* in traditional medicine by hunters and warriors for the treatment of injury. Extracts of *T. bracteolata* leaves have potential to yield active antimicrobial compounds. These observed biological activities may also be the reason why this plant is used as animal feeds. Further studies to investigate the bioactive compounds responsible for the observed biological effects are suggested.
